Department of Dermatology, Hospital del Mar-Parc de Salut Mar, Barcelona, Spain

A 32-year-old man presented with a 2-month history of oral lesions that had been treated with cryotherapy and did not disappear. Physical examination revealed two leukokeratotic plaques with a kissing distribution. No other lesions in the skin or mucosa could be seen. Sexual transmitted diseases serologies, including HIV, syphilis, B and C hepatitis, revealed 1/2 RPR titles with positive *Treponema pallidum* particle agglutination (TPPA). The diagnosis was confirmed with a swab of the lesion for Polymerase Chain Reaction testing for *T. pallidum*. Treatment with a single dose injection of 2.4 million units of benzathine penicillin G was administered and lesions disappeared within 6 weeks (Fig. 1).
